- OSTEP Book by Renzi et al.
- Modern Operating Systems, Tanenbaum et al.
- Other online sources which are duly cited

et al. 1

## How does the Shell work? - Ever thought?

- Init process is started upon hardware initialisation
- The init process spawns a shell like bash
- Shell does the following
  - Read user command
  - Forks a child and exec the command
  - Wait for it to finish -> next command

## Can you think how this works?

- > wc process\_sample3.c > output.txt
- Shell will fork a child
  - Rewires its standard output to text file (output.txt)
  - Calls exec on the child (wc process\_sample.c)
  - The output will be redirected to output.txt
- Have you seen Unix pipes "|"
  - Output of one goes as input to the other

Note: fork() and exec(), both are required

### The Big Question - How to run multiple Processes?

## **Two Major Problems to be Solved**

#### What if we allow process to do whatever it wants?

## How can multiple processes run?

- Hardware Support
  - Have some low level mechanisms to switch process
  - What are the challenges?
    - Performance Overhead?
- Software support
  - Have some policies which decides what needs to be executed
  - What are some of the challenges?
    - Control overhead?

## **Normal Function call**

- Function call translates to a jump instruction
  - One instruction to another instruction
- A new stack frame is pushed to the stack, Stack pointer is updated
- Old value of program counter (return value) pushed to stack and PC is updated
- Stack frame contains return value, function arguments, etc,

### Is this enough?

![](_page_8_Picture_2.jpeg)

	Program
	7 Run main Λ
	8. Execute return from main()
t	

![](_page_8_Picture_4.jpeg)

### What if?

- The process wants to perform operations such as:
  - Issuing I/O request to disk
  - Access to memory or other system resources
- Can we let the process do whatever it wants?

#### **Idea:** Can we think of limiting the access of a process?

![](_page_9_Picture_10.jpeg)

### **Challenge 1: Prevent Unintentional behaviour Limit Direct Execution**

**Only Kernel has access** 

![](_page_10_Picture_2.jpeg)

![](_page_10_Picture_4.jpeg)

![](_page_10_Picture_5.jpeg)

User program can go until this point

![](_page_11_Picture_1.jpeg)

#### Library

- treasured books?

![](_page_11_Picture_6.jpeg)

![](_page_11_Picture_7.jpeg)

Library Users

**Reference** Books

As a visitor/user in the library - check sections, read books, magazines,...

What about accessing the reference section and get access to some

![](_page_11_Picture_12.jpeg)

![](_page_12_Picture_1.jpeg)

![](_page_12_Picture_2.jpeg)

![](_page_12_Picture_3.jpeg)

![](_page_12_Picture_4.jpeg)

![](_page_12_Picture_5.jpeg)

#### **Reference Books Section**

![](_page_12_Picture_7.jpeg)

![](_page_13_Figure_1.jpeg)

![](_page_13_Picture_2.jpeg)

![](_page_13_Picture_3.jpeg)

#### Provides access to the visitor/User as per guidelines

![](_page_13_Picture_5.jpeg)

![](_page_14_Figure_1.jpeg)

#### Access completed

![](_page_14_Picture_3.jpeg)

![](_page_14_Picture_4.jpeg)

![](_page_14_Picture_5.jpeg)

![](_page_14_Picture_6.jpeg)

User is out of the reference section and continues normal access

Librarian waits for next request

![](_page_14_Picture_9.jpeg)

![](_page_14_Picture_11.jpeg)

## **Restricted Operations**

- Bring hardware into the picture
  - Introduce a new processor mode
- User mode
  - Code is restricted in what it can do
  - Eg: no I/O request, Processor will raise an exception
- Kernel mode
  - Code can do whatever it likes to do
  - All privileged operations can be executed

![](_page_15_Picture_9.jpeg)

#### Any challenges that you can think of?

![](_page_15_Picture_12.jpeg)

![](_page_15_Picture_13.jpeg)

![](_page_15_Picture_15.jpeg)

# Limited Direct Execution (LDE)

- Low level mechanism that separates the user space from kernel space Let the program directly run on the CPU
- Limits what process can do
- Offer privileged operations through well defined channels with the help of OS

### At the end we need OS to be more than just a library!

![](_page_16_Picture_6.jpeg)

![](_page_16_Picture_8.jpeg)

![](_page_16_Picture_10.jpeg)

## How to move from User to Kernel?

- System calls Kernel performs on behalf of user process
  - Key pieces of functionality exposed by the kernel
    - File system, process management, process communication, memory allocation, etc
  - Most OS provides few 100s of calls
  - Early unix 20 calls

Some privileged hardware instruction support is needed - Cannot use normal function call mechanism

![](_page_17_Picture_7.jpeg)

## System call works little differently

- Kernel does not trust the user stack You don't want to jump to random addresses
  - Maintains a separate kernel stack (kernel mode)
- Kernel cannot rely on user provided address
  - Uses a table Interrupt Descriptor table (boot time) Guidelines in our example
  - IDT consists of addresses of different kernel functions to run on system calls or other events

![](_page_18_Picture_6.jpeg)

![](_page_18_Picture_7.jpeg)

![](_page_18_Picture_9.jpeg)

![](_page_18_Figure_10.jpeg)

![](_page_18_Picture_11.jpeg)

## **TRAP Instruction**

- Special kind of instruction to switch mode from user to kernel
- Allows system to perform what it wants
- When a system call is made, the trap instruction allows to jump into kernel
  - Raise the privilege mode to kernel mode
  - Return-from-trap instruction allows switch back to user mode
  - Return into the calling user program

Normal routine is interrupted

![](_page_19_Picture_8.jpeg)

![](_page_19_Picture_10.jpeg)

## **More about TRAP instruction**

- During TRAP instruction execution
  - CPU to higher privilege level
  - Switch to Kernel Stack
  - Save context (old PC, registers) on Kernel Stack
  - Look up in IDT (Trap Table) and jump to trap handler function in OS code
  - Once in Kernel, privileged instructions can be performed
- Once done, OS calls a special return-from-trap instruction

Returns into calling program, with back to User mode

![](_page_20_Picture_10.jpeg)

### The dual modes **User Mode and Kernel Mode**

![](_page_21_Figure_1.jpeg)

![](_page_21_Picture_2.jpeg)

Adapted from: OS02-Limited Direct Execution, Dongkun Shin, SKKU

![](_page_21_Picture_4.jpeg)

## **The Dual Modes**

![](_page_22_Figure_1.jpeg)

![](_page_22_Picture_2.jpeg)

#### **User Program**

#include <stdio.h>

int main()

Adapted from: OS02-Limited Direct Execution, Dongkun Shin, SKKU

![](_page_22_Picture_9.jpeg)

## Interrupt and Trap

- Interrupt
  - Signal sent to the CPU due to unexpected event
  - I/O Interrupt, clock Interrupt, Console Interrupt
  - From either Software or Hardware interrupt
    - Hardware may trigger an interrupt by signalling to the CPU
- Trap
  - Software generated interrupt caused by
    - Exception: Error from running program (divide by Zero)
    - System call: Invoked by user program

![](_page_23_Picture_10.jpeg)

### **LDE Protocol**

OS @ boot (Kernel mode)	Hardware	
Initialize trap table	Remember address of Syscall handler	
OS @ run (Kernel mode)	Hardware	Program (User mode)
Create entry for process list Allocate memory for program Load program into memory Setup user stack with arg Fill kernel stack with reg/PC		
	Restore regs from kernel stack Move to user mode Jump to main	
		Run main()
		System call trap into OS
	25	Softwar

![](_page_24_Picture_3.jpeg)

### **LDE Protocol**

OS @ boot (Kernel mode)	Hardware	Program (User mod
	Save reas to kernel stack	
	Save reys to kernel mode	
	Nove to kernel mode	
	Jump to trap handler	
Handle tran		
Execute the evetem cell		
Return-trom-trap		
	Restore regs from kernel stack	
	Move to user mode	
	Jump to PC after trap	
		 Return from main()
		trap (via exit())
Erec memory of process		
Free memory of process		
Remove process from process list		
	26	

![](_page_25_Picture_3.jpeg)

### **Problem 2: How to Switch between Process?** Lets draw some parallels

![](_page_26_Picture_1.jpeg)

Librarian does not have a control when the person is inside the reference section (only one reference section and a person is already inside)

How can this situation be handled? - What can be the possibilities?

![](_page_26_Picture_4.jpeg)

![](_page_26_Picture_5.jpeg)

More users/visitors have requested to access the reference section

![](_page_26_Picture_7.jpeg)

### **Cooperative Approach** Non-Preemptive

- Wait for system calls
- OS trusts the processes to behave reasonably (Give control back Yield() call)
- Process transfer the control to the CPU by making a system call
- There can be misbehaving process (They may try to do something they shouldn't)
  - Divide by zero or attempting to access memory it shouldn't
  - Trap to OS -> OS will terminate the process
- Used in initial versions of Mac OS, Old Xerox alto system
- What if there is an infinite loop & process never terminates? Reboot

![](_page_27_Picture_9.jpeg)

### Non-Cooperative Approach Preemptive

- OS takes control
  - The only way in cooperative approach to take control is reboot
  - Without Hardware support, OS can't do much!
  - How can OS gain control?
- Simple solution Use interrupts
  - Timer interrupt was invented many years ago
  - handler -> OS regains control

• Every X milliseconds, raise an interrupt -> halt the process -> invoke interrupt

![](_page_28_Picture_12.jpeg)

![](_page_28_Picture_14.jpeg)

### **Non-Cooperative Approach** Preemptive - Timer Interrupt

- During boot sequence, OS starts the timer
- The time raises an interrupt every "X" milliseconds
- The timer interrupt gives OS the ability to run again on CPU
- Two decisions are possible Component called Scheduler comes into picture
  - Continue with current process after handling interrupt
  - Switch to a different process => OS executes Context Switch

![](_page_29_Picture_7.jpeg)

![](_page_29_Picture_8.jpeg)

## **Context Switch**

- A low-level piece of assembly code
- Save a few register values from executing process registers to kernel stack
  - General purpose registers
  - Program counter
  - Kernel stack pointer
- Restore values for the next process
  - essentially retrun-from-trap will go to new process

Switch to Kernel stack for the next process

![](_page_30_Figure_9.jpeg)

![](_page_30_Picture_11.jpeg)

![](_page_30_Picture_12.jpeg)

![](_page_30_Picture_15.jpeg)

## LDE Protocol (Timer Interrupt)

![](_page_31_Figure_1.jpeg)

Hardware	
ember address of Syscall handler Timer handler	
Start timer PU every "X" milliseconds	
Hardware	Program (User mode)
	Process A
Timer interrupt regs(A) to k-stack(A) ve to kernel mode np to trap handler	S

![](_page_31_Picture_4.jpeg)

## LDE Protocol (Timer Interrupt)

OS @ boot (Kernel mode)	Hardware	Program (User mode)
Handle the trap Call switch() routine Save regs(A) to proc-struct(A) Restore regs(B) from proc-struct(B) Switch to k-stack(B) <b>Return-from-trap (into B)</b>		
	Restore regs(B) from k-stack(B) Move to user mode Jump to B's PC	
		Process B 

![](_page_32_Picture_3.jpeg)

### What if?

- During handling of one interrupt another interrupt occurs?
  - Disable interrupt during interrupt processing
  - Sophisticated locking mechanism to protect concurrent access to internal data structures

### How to decide which process to run next?

![](_page_33_Picture_5.jpeg)

![](_page_33_Picture_6.jpeg)
